

In Python, an **expression** is any combination of values, variables, operators, and function calls that can be evaluated to produce a **single value**. Unlike statements (which execute actions or commands), every single expression always reduces down to a specific data result .

Expression produces a value, while a statement performs an action.

Eg:

```
1 result = 5 + 2
2 print(result)
3
```

```
7
```

Here:

- `5 + 2` → **Expression**
- `result = 5 + 2` → **Statement** (assignment statement)

Expression

`5 + 2`

`10 > 5`

`x * 2`

`"Hello" + "World"`

Statement

`x = 5 + 2`

`if x > 5:`

`print(x)`

`x = "Hello"`
